initial population $n<256$
every $m$ th person is executed; $m>1$
two additional temporary registers

Sequence number
A counter
Current element
Number of empty slots in out Output 8 characters
maximal $2 * 9+3 * 90+4 * 157=916$ bytes top of circle for N bytes

1 Store distance to next man in circle.
$\lceil n / 8\rceil$ Link each byte with next byte.
$\lceil n / 8\rceil 8$ links done.
$\lceil n / 8\rceil$
1 Last byte jumps back to the first.
1 Start execution; no one excluded so far.
1 Start with first person.
$n-1$ Count down $m-2$ links.
$P \quad$ Get distance from cur to next person
$P \quad$ and follow the link to this person.
P
$P$
$n-1$ cur survives the round,
$n-1$ but the next man cnt is executed.
$n-1$ Get his neighbor.
$n-1$ Add it to previous distance for cur.
$n-1$ Store the new value for cur.
$n-1$ Move to next man for next round.
$n-1$ Increase the sequence number
$n-1$ and store it for the executed man.
$n-1$ Is only one person left?
$n-1$ If not start count down again.
1 He is the last man
1 and gets the number $n$.
1 Start the output with first man.
18 chars in out are empty.
1 Offset in _buf to store out.
$n$ Load next sequence number.
$D$ Extract
$D$ the digits
$D$ from right
$D$ to left
$D \quad$ and store them in the register ttt .
D
$n \quad$ Add a space in front of each sequence number.

| 53 |  | JMP | 9F | $n$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 54 | 1H | AND | t,ttt, \#ff | D | Move ttt in reverse order to out. |

## Analysis

The output of the programm is: $15 \begin{array}{llllllllllllllllllll}12 & 22 & 8 & 16 & 11 & 23 & 21 & 3 & 5 & 1 & 17 & 10 & 7 & 24 & 19 & 20 & 18 & 9 & 14 & 4\end{array} 2136$. So the last man is at position 15 . The statistics at the end of the run is: 1879 instructions, 336 mems, 4350 oops; 341 good guesses, 81 bad.

In general the program needs $(5 n+\lceil n / 8\rceil+\lfloor(D+n) / 8\rfloor+P-1) \mu+(27 n+3\lceil n / 8\rceil+6\lfloor(D+n) / 8\rfloor+$ $4 P+72 D+15) v$. The value $P$ stands for $n-1$ count downs of $m-2$ steps, that is $P=(n-1)(m-2)$. The quantity $D$ is the number of decimal digits in the output:

$$
D=\sum_{i=0}^{\left\lfloor\log _{10} n\right\rfloor-1} 9 \cdot 10^{i}+\left(\left\lfloor\log _{10} n\right\rfloor+1\right)\left(n+1-10^{\left\lfloor\log _{10} n\right\rfloor}\right)
$$

In the case $n=24, m=11$ the values of $P$ and $D$ are $23 \cdot 9=207$ and $9+2 \cdot 15=39$. Therefore in this case the program would need $(120+3+7+207-1) \mu=336 \mu$ and $(648+9+42+828+2808+15) v=4350 v$ which agrees with the measured data.
